approximating real numbers with rational numbers In number theory, the study of Diophantine approximation deals with the approximation of real numbers by rational numbers. It is named after Diophantus of Alexandria. The first problem was to know how well a real number can be approximated by rational numbers. For this problem, a rational number  $a/b$  is a "good" approximation of a real number  $\alpha$  if the absolute value of the difference between  $a/b$  and  $\alpha$  may not decrease if  $a/b$  is replaced by ...

Diophantine approximation is a branch of number theory originally created by Diophantus for estimating any given real number as a ratio of two integers. Much of the current research into this topic is on whether or not this theory can be applied to algebraic numbers.

In number theory, Dirichlet's theorem on Diophantine approximation, also called Dirichlet's approximation theorem, states that for any real numbers  $\alpha$  and  $\beta$ , with  $\alpha \neq \beta$ , there exist integers  $p$  and  $q$  such that  $|p\alpha - q\beta| < \frac{1}{q^2}$  and  $q > 0$ .

Abstract The present thesis reveals a novel connection of Diophantine approximation arising from small divisors to general relativity, more precisely, the Strong Cosmic Censorship conjecture. The main results provide theorems which resolve a linear scalar analog of the Strong Cosmic Censorship conjecture in general relativity for  $\epsilon < 0$ .
