number of TURNS around the coil that is producing the magnetic flux within the core, and to the amount of CURRENT flowing in the coil. Therefore the amount of flux, Φ (The Greek letter Phi) is proportional to the product of N (number of turns) x I (the current in amperes) or the 'AMPERE TURNS' of the coil.

A Transformer changes the voltage level (or current level) on its input winding to another value on its output winding using a magnetic field. A transformer consists of two electrically isolated coils and operates on Faraday ' s principal of “ mutual induction ” , in which an EMF is induced in the transformers secondary coil by the magnetic flux generated by the voltages and

Transformer Basics and Transformer Principles
Practically all electric power machinery (e.g. transformers, generators, motors) depend for their operation upon the magnetism produced by the magnetic circuits. The closed path followed by magnetic flux is called a magnetic circuit (Fig. 1) just as the closed path followed by current is called an electric circuit.

A magnetic circuit is made up of one or more closed loop paths containing a magnetic flux. The flux is usually generated by permanent magnets or electromagnets and confined to the path by magnetic cores consisting of ferromagnetic materials like iron, although there may be air gaps or other materials in the path. Magnetic circuits are employed to efficiently channel magnetic fields in many devices such as electric motors, generators, transformers, relays, lifting electromagnets, SQUIDs, galvanom
