There should be no open circuit on the secondary side of the current transformer in operation. Once the open circuit occurs on the secondary side, high temperature caused by excessive iron loss may burn out the current transformer or enhance the voltage of secondary winding, thus breaking down the insulation and leading to the danger of high voltage electric shock.

Check the transformer's output voltage. Connect the transformer's primary to a 110-volt source using the Test Jumper. Be careful that the Alligator clips don't touch one another or touch some grounded surface. Do not touch the clips or the primary terminals once the cord is plugged in, as you could receive a fatal shock.

Check both windings. Many transformers have a fuse on the 24 volt side. If the fuse is open, the ohmmeter will read no continuity. There is a probably a short in the 24 volt circuit. Replacement of the transformer will not solve the problem. The new transformer will also fail. I recommend using a transformer without a built in fuse.
